10ACC SERIES UNITS

The 10ACC is a residential split-system condensing unit available in sizes ranging from 1-1/2 to 5 tons. Condensing coil size, circuiting and air volume result in a minimum SEER rating of 10.0. The series is designed for use with an expansion valve or RFCIV system in the indoor unit.

10ACC units are equipped with either a reciprocating compressor or scroll compressor. All compressors are hermetically sealed for long service life. The compressor is installed in the unit on resilient rubber mounts to assure quiet, vibration-free operation. A built-in protection device assures protection from excessive current and temperatures.

The scroll operates like a standard compressor but it is unique in the way it compresses refrigerant.

This manual is divided into sections which discuss the major components, refrigerant system, charging procedure, maintenance and operation sequence.

All specifications in this manual are subject to change.

**WARNING**

Electric shock hazard. Can cause injury or death. Before attempting to perform any service or maintenance, turn the electrical power to unit OFF at disconnect switch(es). Unit may have multiple power supplies.

**IMPORTANT**

Improper installation, adjustment, alteration, service or maintenance can cause property damage, personal injury or loss of life. Installation and service must be performed by a qualified installer or service agency.

**IMPORTANT**

The Clean Air Act of 1990 bans the intentional venting of (CFC's and HFC's) as of July 1, 1992. Approved methods of recovery, recycling or reclaiming must be followed. Fines and/or incarceration may be levied for noncompliance.

**WARNING**

Refrigerant can be harmful if it is inhaled. Refrigerant must be used and recovered responsibly. Failure to follow this warning may result in personal injury or death.

### Compressor

- Rated load amps: 8.6, 10.8, 12.2, 12.9, 14.1, 16.2, 17.9, 21.8, 26.6
- Locked rotor amps: 49.0, 60, 61, 69.4, 73.0, 96, 103, 131, 170
- Power factor: 0.97, 0.96, 0.96, 0.92, 0.95, 0.90, 0.84, 0.80, 0.90

### Condenser Fan Motor

- Full load amps: 0.8, 0.8, 0.8, 1.1, 0.8, 1.7, 1.9, 1.9, 0.9
- Locked rotor amps: 1.2, 1.2, 1.2, 1.9, 1.2, 3.1, 4.1, 4.1, 4.1

### Specfications

### General Data

- Nominal Tonnage (kW): 1.5 (5.3), 2 (7.0), 2.5 (8.8), 3 (10.6), 3.5 (12.3), 4 (14.1), 5 (17.6)

### Connections (sweat)

### Refrigerant

- Charge furnished: 3 lbs. 7 oz. (1.56 kg), 3 lbs. 9 oz. (1.62 kg), 3 lbs. 10 oz. (1.64 kg), 4 lbs. 10 oz. (2.12 kg), 5 lbs. 1 oz. (2.28 kg), 6 lbs. 0 oz. (2.72 kg), 8 lbs. 2 oz. (3.67 kg)

### Condenser

- Net face area - sq. ft. (m²): 10.0 (0.93), 10.0 (0.93), 10.0 (0.93), 11.41 (1.06), 13.31 (1.24), 15.11 (1.40), 20.83 (1.94)
- Tube diameter - in. (mm): 5/16 (7.9), 5/16 (7.9), 5/16 (7.9), 5/16 (7.9), 5/16 (7.9), 5/16 (7.9), 5/16 (7.9)
- No. of rows: 1
- Fins per inch (m): 18 (709), 18 (709), 18 (709), 22 (866), 22 (866), 22 (866), 22 (866)

### Condenser Fan

- Diameter - in. (mm): 16 (406), 16 (406), 18 (457), 18 (457), 18 (457), 18 (457), 22 (559)
- No. of blades: 3
- Motor hp (W): 1/10 (75), 1/10 (75), 1/10 (75), 1/4 (187), 1/3 (249), 1/3 (249), 1/3 (249)
- Cfm (L/s): 1070, 1070, 1070, 1103, 1116, 1160, 1100
- Watts: 184, 184, 184, 266, 299, 310, 367

### Shipping weight (1 package)

- lbs. (kg): 126 (57), 107 (49), 107 (49), 140 (64), 140 (64), 196 (89), 199 (90)

### Optional Accessories - MUST BE ORDERED EXTRA

- Crankcase Heater: 68887, 90P12, 90P12, 68887, 90P12, 90P12, 90P12
- Hall Guards: 17L71, 17L71, 17L71, 17L73, 17L73, 17L73, 17L73
- Low Ambient Kit (for Expansion Valve systems only): 24H77, 24H77, 24H77, 24H77, 24H77, 24H77, 24H77
- Mounting Base: Model No. MB2-S (69J06) 6 lbs. (3 kg), Dimensions - in. (mm) 22-1/4x22-1/4x3 (565 x 565x76)
- Timed-Off Control: LB-61378A (47J35)
- Unit Stand-Off Kit: 94J45, 94J45, 94J45, 94J45, 94J45, 94J45, 94J45
- Unit Hard-Start Kit: 64J09, 10J42, 10J42, 64J09, 81J69, 81J69, 81J69
- Compressor Monitor (Canada only): 16-1469 (45F08)

---

*Refrigerant charge sufficient for 15 ft. (4.5 m) length of refrigerant lines.

---

/C0019

3/8 in. x 5/16 in. (9.5 mm x 7.9 mm) reducer bushing (not furnished) is required for liquid line connection.
I - GENERAL

DANGER

Make sure all power is disconnected before beginning electrical service procedures.

10ACC condensing units are available in 1-1/2, 2, 2-1/2, 3, 3-1/2, 4 and 5 ton capacities.

All major components (indoor blower and coil) must be matched according to Lennox recommendations for the compressor to be covered under warranty. Refer to the Engineering Handbook for approved system matchups. A misapplied system will cause erratic operation and can result in early compressor failure.

II - UNIT COMPONENTS

Unit components are illustrated in figure 1.
A - Control Box (Figures 2 & 3)
Electrical openings are provided under the control box cover. Field thermostat wiring is made to color-coded pigtail connections.

1 - Compressor Contact K1
The compressor is energized by a contactor located in the control box. See figure 2. Single-pole contactors are used in 10ACC units. K1 is energized by the indoor thermostat terminal Y1 (24V) when thermostat demand is present. 10ACC units are not equipped with a 24V transformer. All 24 VAC controls are powered by the indoor unit. Refer to wiring diagram.

DANGER
Electric Shock Hazard.
May cause injury or death.
Line voltage is present at all components when unit is not in operation on units with single pole contactors.
Disconnect all remote electrical power supplies before opening unit panel.
Unit may have multiple power supplies.

2 - Dual Capacitor C12
The compressor and fan in 10ACC series units use permanent split capacitor motors. The capacitor is located inside the unit control box (see figures 2 and 3). A single “dual” capacitor (C12) is used for both the fan motor and the compressor (see unit wiring diagram). The fan side and the compressor side of the capacitor have different MFD ratings. For ratings see side of capacitor.

3 - Start Capacitor C7 (option)
Start capacitor (C7) is wired in parallel with the compressor side of the dual capacitor. The capacitor is located inside the unit control box (see figure 2). C7 is switched off by potential relay (K31) when the compressor nears full speed. The start capacitor is rated at 330 VAC and has an MFD rating of 176-216.

4 - Potential (Start) Relay K31 (option)
Potential relay K31 is located inside the unit control box (see figure 2). The relay is normally closed when contactor K1 is de-energized. When K1 energizes, the compressor immediately begins start-up. K31 remains closed during compressor start-up and the start capacitor C7 remains in the circuit. When the compressor reaches 75% of its speed, K31 is energized. When K31 energizes, the contacts open and the start capacitor C7 is taken out of the circuit.
B - Compressor
For compressor specifications see “ELECTRICAL DATA” section in this manual or the compressor name-plate.

![SCROLL COMPRESSOR](image)

**FIGURE 4**

1 - Scroll Compressor
The scroll compressor design is simple, efficient and requires few moving parts. A cutaway diagram of the scroll compressor is shown in figure 4. The scrolls are located in the top of the compressor can and the motor is located just below. The oil level is immediately below the motor.

The scroll is a simple compression concept centered around the unique spiral shape of the scroll and its inherent properties. Figure 5 shows the basic scroll form. Two identical scrolls are mated together forming concentric spiral shapes (figure 6). One scroll remains stationary, while the other is allowed to “orbit” (figure 7). Note that the orbiting scroll does not rotate or turn but merely “orbits” the stationary scroll.

![SCROLL FORM](image)

**FIGURE 5**

The counterclockwise orbiting scroll draws gas into the outer crescent shaped gas pocket created by the two scrolls (figure 7 - 1). The centrifugal action of the orbiting scroll seals off the flanks of the scrolls (figure 7 - 2). As the orbiting motion continues, the gas is forced toward the center of the scroll and the gas pocket becomes compressed (figure 7 - 3). When the compressed gas reaches the center, it is discharged vertically into a chamber and discharge port in the top of the compressor (figure 6). The discharge pressure forcing down on the top scroll helps seal off the upper and lower edges (tips) of the scrolls (figure 6). During a single orbit, several pockets of gas are compressed simultaneously providing smooth continuous compression.

The scroll compressor is tolerant to the effects of liquid return. If liquid enters the scrolls, the orbiting scroll is allowed to separate from the stationary scroll. The liquid is worked toward the center of the scroll and is discharged. If the compressor is replaced, conventional Lennox cleanup practices must be used.

Due to its efficiency, the scroll compressor is capable of drawing a much deeper vacuum than reciprocating compressors. Deep vacuum operation can cause internal fuse site arcing resulting in damaged internal parts and will result in compressor failure. Never use a scroll compressor for evacuating or “pumping-down” the system. This type of damage can be detected and will result in denial of warranty claims.

*NOTE - During operation, the head of a scroll compressor may be hot since it is in constant contact with discharge gas.*
**C - Condenser Fan Motor**

All units use single-phase PSC fan motors which require a run capacitor. In all units, the condenser fan is controlled by the compressor contactor.

ELECTRICAL DATA tables in this manual show specifications for condenser fans used in 10ACCs.

Access to the condenser fan motor on all units is gained by removing the seven screws securing the fan assembly. See figure 8. The condenser fan motor is removed from the fan guard by removing the four nuts found on the top panel. See figure 9 if condenser fan motor replacement is necessary.

**III - REFRIGERANT SYSTEM**

**A - Plumbing**

Field refrigerant piping consists of liquid and suction lines from the condensing unit (sweat connections) to the indoor evaporator coil (flare or sweat connections). Use Lennox L15 (sweat, non-flare) series line sets as shown in table 1 or use field-fabricated refrigerant lines.

Separate discharge and suction service ports are provided outside the unit for connection of gauge manifold during charging procedure.

*Field fabricate. See Corp. 9351-L9 Refrigerant Piping
B - Service Valves

The liquid and vapor line service valves (figures 10 and 11) and gauge ports are accessible from outside the unit.

The valve is equipped with a service port. The service ports are used for leak testing, evacuating, charging, and checking charge. A schrader valve is factory installed. A service port cap is supplied to protect the schrader valve from contamination and serve as the primary leak seal.

*NOTE-Always keep valve stem caps clean.*

To Access Schrader Port:
1. Remove service port cap with an adjustable wrench.
2. Connect gauge to the service port.
3. When testing is completed, replace service port cap. Tighten finger tight, then an additional 1/6 turn.

To Open Liquid or Vapor Line Service Valve:
1. Remove stem cap with an adjustable wrench.
2. Using service wrench and hex head extension (3/16 for liquid line and 5/16 for vapor line) back the stem out counterclockwise until the valve stem just touches the retaining ring.
3. Replace stem cap tightly. Tighten finger tight, then tighten an additional 1/6 turn.

To Close Liquid or Vapor Line Service Valve:
1. Remove stem cap with an adjustable wrench.
2. Using service wrench and hex head extension (3/16 for liquid line and 5/16 for vapor line), turn stem clockwise to seat the valve. Tighten firmly.
3. Replace stem cap. Tighten finger tight, then tighten an additional 1/6 turn.

Vapor Line (Ball Type) Service Valve (5 Ton Only)

A ball-type full service valve is used on 10ACC 5 ton units. These suction line service valves function the same way, differences are in construction. Valves are not rebuildable. If a valve has failed it must be replaced. A ball valve is illustrated in figure 11.

The ball valve is equipped with a service port. A schrader valve is factory installed. A service port cap is supplied to protect the schrader valve from contamination and assure a leak free seal.
IV - CHARGING

A - Pumping Down System

**CAUTION**

Deep vacuum operation (operating compressor at 0 psig or lower) can cause internal fusite arcing resulting in a damaged or failed compressor. This type of damage will result in denial of warranty claim.

The system may be pumped down when leak checking the line set and indoor coil or making repairs to the line set or indoor coil.

1. Attach gauge manifold.
2. Front seat (close) liquid line valve.
3. Start outdoor unit.
4. Monitor suction gauge. Stop unit when 0 psig is reached.
5. Front seat (close) suction line valve.

B - Leak Testing (To Be Done Before Evacuating)

After the line set has been connected to the indoor and outdoor units, check the line set connections and indoor unit for leaks.

**WARNING**

Refrigerant can be harmful if it is inhaled. Refrigerant must be used and recovered responsibly. Failure to follow this warning may result in personal injury or death.

**WARNING**

Danger of explosion: Can cause equipment damage, injury or death. Never use oxygen to pressurize a refrigeration or air conditioning system. Oxygen will explode on contact with oil and could cause personal injury.

**WARNING**

Danger of explosion: Can cause equipment damage, injury or death. When using a high pressure gas such as dry nitrogen to pressurize a refrigeration or air conditioning system, use a regulator that can control the pressure down to 1 or 2 psig (6.9 to 13.8 kPa).

Using an Electronic Leak Detector or Halide

1. Connect a cylinder of HCFC-22 to the center port of the manifold gauge set.
2. With both manifold valves closed, open the valve on the HCFC-22 cylinder (vapor only).
3. Open the high pressure side of the manifold to allow the HCFC-22 into the line set and indoor unit. Weigh in a trace amount of HCFC-22. [A trace amount is a maximum of 2 ounces (57 g) or 3 pounds (31 kPa) pressure.] Close the valve on the HCFC-22 cylinder and the valve on the high pressure side of the manifold gauge set. Disconnect the HCFC-22 cylinder.
4. Connect a cylinder of nitrogen with a pressure regulating valve to the center port of the manifold gauge set.
5. Connect the manifold gauge set high pressure hose to the vapor valve service port. *(Normally, the high pressure hose is connected to the liquid line port; however, connecting it to the vapor port better protects the manifold gauge set from high pressure damage.)*
6. Adjust the nitrogen pressure to 150 psig (1034 kPa). Open the valve on the high side of the manifold gauge set which will pressurize line set and indoor unit.
7. After a few minutes, open a refrigerant port to ensure the refrigerant you added is adequate to be detected. *(Amounts of refrigerant will vary with line lengths.)* Check all joints for leaks. Purge nitrogen and HCFC-22 mixture. Correct any leaks and recheck.

C - Evacuating the System

Evacuating the system of noncondensables is critical for proper operation of the unit. Noncondensables are defined as any gas that will not condense under temperatures and pressures present during operation of an air conditioning system. Noncondensables and water vapor combine with refrigerant to produce substances that corrode copper piping and compressor parts.

**NOTE** - This evacuation process is adequate for a new installation with clean and dry lines. If excessive moisture is present, the evacuation process may be required more than once.

**IMPORTANT**

Use a thermocouple or thermistor electronic vacuum gauge that is calibrated in microns. Use an instrument that reads from 50 microns to at least 10,000 microns.

1. Connect manifold gauge set to the service valve ports:
   - low pressure gauge to vapor line service valve
   - high pressure gauge to liquid line service valve
2. Connect micron gauge.
3. Connect the vacuum pump (with vacuum gauge) to the center port of the manifold gauge set.
4. Open both manifold valves and start the vacuum pump.
5. Evacuate the line set and indoor unit to an absolute pressure of 23,000 microns (29.01 inches of mercury). During the early stages of evacuation, it is desirable to close the manifold gauge valve at least once to determine if there is a rapid rise in absolute pressure. A rapid rise in pressure indicates a relatively large leak. If this occurs, repeat the leak testing procedure.
NOTE − The term **absolute pressure** means the total actual pressure within a given volume or system, above the absolute zero of pressure. Absolute pressure in a vacuum is equal to atmospheric pressure minus vacuum pressure.

6 - When the absolute pressure reaches 23,000 microns (29.01 inches of mercury), close the manifold gauge valves, turn off the vacuum pump and disconnect the manifold gauge center port hose from vacuum pump. Attach the manifold center port hose to a nitrogen cylinder with pressure regulator set to 150 psig (1034 kPa) and purge the hose. Open the manifold gauge valves to break the vacuum in the line set and indoor unit. Close the manifold gauge valves.

### CAUTION

Danger of Equipment Damage.
Avoid deep vacuum operation. Do not use compressors to evacuate a system.
Extremely low vacuums can cause internal arcing and compressor failure.
Damage caused by deep vacuum operation will void warranty.

7 - Shut off the nitrogen cylinder and remove the manifold gauge hose from the cylinder. Open the manifold gauge valves to release the nitrogen from the line set and indoor unit.

8 - Reconnect the manifold gauge to the vacuum pump, turn the pump on, and continue to evacuate the line set and indoor unit until the absolute pressure does not rise above 500 microns (29.9 inches of mercury) within a 20-minute period after shutting off the vacuum pump and closing the manifold gauge valves.

9 - When the absolute pressure requirement above has been met, disconnect the manifold hose from the vacuum pump and connect it to an upright cylinder of HCFC-22 refrigerant. Open the manifold gauge valves to break the vacuum from 1 to 2 psig positive pressure in the line set and indoor unit. Close manifold gauge valves and shut off the HCFC-22 cylinder and remove the manifold gauge set.

### D - Charging

Units are factory charged with the amount of HCFC-22 refrigerant indicated on the unit nameplate. This charge is based on a matching indoor coil and outdoor coil with a 15 ft. (4.5 m) line set. For varying lengths of line set, refer to table 2 for refrigerant charge adjustment. A blank space is provided on the nameplate to list the actual field charge.

<table>
<thead>
<tr>
<th>Liquid Line Set Diameter</th>
<th>Oz. per 5 ft. (g per 1.5 m) adjust from 15 ft. (4.5 m) line set*</th>
</tr>
</thead>
<tbody>
<tr>
<td>3/8 in. (10 mm)</td>
<td>3 ounce per 5 ft. (85g per 1.5 m)</td>
</tr>
</tbody>
</table>

*If line length is greater than 15 ft. (4.5 m), add this amount. If line length is less than 15 ft. (4.5 m), subtract this amount.

The condensing unit should be charged during warm weather. However, applications arise in which charging must occur in the colder months. The method of charging is determined by the unit's refrigerant metering device and the outdoor ambient temperature.

Measure the liquid line temperature and the outdoor ambient temperature as outlined below:

1. - Connect the manifold gauge set to the service valves: low pressure gauge to suction valve service port; high pressure gauge to liquid valve service port. Connect the center manifold hose to an upright cylinder of HCFC-22. Close manifold gauge set valves.
2. - Set the room thermostat to call for heat. This will create the necessary load for properly charging the system in the cooling cycle.
3. - Use a digital thermometer to record the outdoor ambient temperature.
4. - When the heating demand has been satisfied, switch the thermostat to cooling mode with a set point of 68°F (20°C). When pressures have stabilized, use a digital thermometer to record the liquid line temperature.
5. - The outdoor temperature will determine which charging method to use. Proceed with the appropriate charging procedure.

### Weighing in the Charge Fixed Orifice or TXV Systems – Outdoor Temp < 60°F (16°C)

If the system is void of refrigerant, or if the outdoor ambient temperature is cool, the refrigerant charge should be weighed into the unit according to the total amount shown on the unit nameplate. This may be done after any leaks have been repaired. If weighing facilities are not available or if unit is being charged during warm weather, follow one of the other procedures outlined below.

1 - Recover the refrigerant from the unit.
2 - Conduct a leak check, then evacuate as previously outlined.
3 - Weigh in the factory charge according to the amount recorded on the outdoor unit nameplate.

### Approach and Normal Operating Pressures

**TXV Systems – Outdoor Temp. ≥ 65°F (18°C)**

The following procedure is intended as a general guide and is for use on expansion valve systems only. For best results, indoor temperature should be 70°F (21°C) to 80°F (26°C). Monitor system pressures while charging.

1 - Record outdoor ambient temperature using a digital thermometer.
2 - Attach high pressure gauge set and operate unit for several minutes to allow system pressures to stabilize.

3 - Compare stabilized pressures with those provided in table 5, “Normal Operating Pressures.” Minor variations in these pressures may be expected due to differences in installations. Significant differences could mean that the system is not properly charged or that a problem exists with some component in the system. Pressures higher than those listed indicate that the system is overcharged. Pressures lower than those listed indicate that the system is undercharged. Verify adjusted charge using the approach method.

4 - Outdoor temperature should be 65°F (18°C) or above. Use the same digital thermometer used to check outdoor ambient temperature to check liquid line temperature. Verify the unit charge using the approach method. The difference between the ambient and liquid temperatures should match values given in table 3. Refrigerant must be added to lower approach temperature and removed to increase approach temperature. Loss of charge results in low capacity and efficiency.

5 - If the values don’t agree with the those in table 3, add refrigerant to lower the approach temperature or recover refrigerant from the system to increase the approach temperature.

### Charging Using the Subcooling Method

**Fixed Orifice Systems – Outdoor Temp. > 65°F (18°C)**

If you charge a fixed orifice system when the outdoor ambient is 65°F (18°C) or above, use the subcooling method to charge the unit.

1 - With the manifold gauge hose still on the liquid service port and the unit operating stably, use a digital thermometer to record the liquid line temperature.

2 - At the same time, record the liquid line pressure reading.

3 - Use a temperature/pressure chart for HCFC-22 to determine the saturation temperature for the liquid line pressure reading.

4 - Subtract the liquid line temperature from the saturation temperature (according to the chart) to determine subcooling. (Saturation temperature - Liquid line temperature = Subcooling)

5 - Compare the subcooling value with those in table 4. If subcooling is greater than shown, some refrigerant must be recovered. If subcooling is less than shown, some refrigerant must be added.

*These are typical pressures only. Indoor evaporator match up, indoor air quality, and evaporator load will cause the pressures to vary.

1 Tecumseh compressor 2 Copeland compressor

**IMPORTANT**

Use table 5 to perform maintenance checks. Table 5 is not a procedure for charging the system. Minor variations in these pressures may be due to differences in installations. Significant deviations could mean that the system is not properly charged or that a problem exists with some component in the system. See table 5.

V - Maintenance

**WARNING**

Electric shock hazard. Can cause injury or death. Before attempting to perform any service or maintenance, turn the electrical power to unit OFF at disconnect switch(es). Unit may have multiple power supplies.

Maintenance and service must be performed by a qualified installer or service agency. At the beginning of each cooling season, the system should be checked as follows:

1 - Clean and inspect the condenser coil. The coil may be flushed with a water hose. Make sure power is off before cleaning.

2 - Visually inspect connecting lines and coils for evidence of oil leaks.

3 - Check wiring for loose connections.

4 - Check for correct voltage at unit (unit operating).

5 - Check the compressor and condenser fan motor amp-draw.

NOTE - If the owner complains of insufficient cooling, the unit should be gauged and the refrigerant charge should be checked. Refer to the charging section in this instruction.

Evaporator Coil

1 - Clean coil, if necessary.

2 - Check connecting lines and coils for evidence of oil leaks.

3 - Check the condensate pan line and clean it if necessary.

Indoor Unit

1 - Clean or change filters.

2 - Adjust blower speed for cooling. The pressure drop over the coil should be measured to determine the correct blower CFM. Refer to the unit information service manual for pressure drop tables and procedure.

3 - Belt Drive Blowers - Check belt for wear and proper tension.

4 - Check all wiring for loose connections.

5 - Check for correct voltage at unit (blower operating).

6 - Check amp-draw on blower motor.
NOTE - The thermostat used may be electromechanical or electronic.

NOTE - Transformer in indoor unit supplies power (24 VAC) to the thermostat and outdoor unit controls.

COOLING:
1. Cooling demand initiates at Y1 in the thermostat.
2. 24VAC energizes compressor contactor K1.
3. K1-1 N.O. closes, energizing compressor (B1) and outdoor fan motor (B4).
4. Compressor (B1) and outdoor fan motor (B4) begin immediate operation.

END OF COOLING DEMAND:
5. Cooling demand is satisfied. Terminal Y1 is de-energized.
6. Compressor contactor K1 is de-energized.
7. K1-1 opens and compressor (B1) and outdoor fan motor (B4) are de-energized and stop immediately.
