The HP24 is a high-efficiency residential split-system heat pump. Extra large outdoor coil, coil circuiting and high outdoor coil air volume result in a high SEER rating (minimum of 10.0). HP24-141 through HP24-510 units are designed for use with an expansion valve or RFCIII system in the indoor unit. HP24-651/653 units are designed for use with an expansion valve only in the indoor unit.

All compressors are hermetically sealed for trouble-free operation and long service life. Compressor components are spring mounted within the sealed housing. The compressor is installed in the unit on resilient rubber mounts to assure quiet, vibration-free operation. A built-in limit protects the compressor from excessive current and temperatures.

HP24-211 through HP24-650 models are furnished with crankcase heaters as standard equipment. The heater prevents liquid from accumulating in the compressor. The heater is temperature-actuated and operates only when required. A crankcase heater for HP24-141 units is optional, but suction accumulator is factory installed.

Several models are available in sizes ranging from 1 through 5 tons.

This manual is divided into sections which discuss the major components, refrigerant system, charging procedure, maintenance, and operation sequence. Canadian specifications are marked (CAN).

All specifications in this manual are subject to change.

1. Units manufactured before September 1, 1992 have a sufficient charge for a 20ft. line set. Units manufactured after September 1, 1992 have sufficient charge for a 20ft. line set. Refer to unit nameplate for factory supplied charge.

2. Refer to National Electric Code manual to determine wire, fuse and disconnect size requirements.

### I - UNIT INFORMATION

HP24 units are available in 1, 1-1/2, 2, 2-1/2, 3, 3-1/2, 4 and 5 ton capacities.

All major components (indoor blower/coil) must be matched according to Lennox recommendations for the compressor to be covered under warranty. Refer to the Engineering Handbook for approved system matchups. A misapplied system will cause erratic operation and can result in early compressor failure.

### II - UNIT COMPONENTS

Unit components are illustrated in figure 1.
A - Control Box (Figures 2 and 3)

![Diagram of HP24 Unit Control Box Single Phase Units](image)

**FIGURE 2**

HP24 UNIT CONTROL BOX THREE PHASE UNITS

![Diagram of HP24 Unit Control Box Three Phase Units](image)

**FIGURE 3**

A low voltage make up area is provided for thermostat field wiring. Field thermostat wiring is made to color coded pigtail connections as illustrated in figure 4.

![Thermostat Wiring Identification](image)

**FIGURE 4**

**WARNING**

Shock Hazard

All single phase HP24 units use single-pole contactors. One leg of compressor, capacitor and outdoor fan are connected to line voltage at all times. Potential exists for electrical shock resulting in injury or death. Remove all power at disconnect before servicing. Can cause personal injury or death.

1 - Compressor Contactor K1

The compressor is energized by a contactor located in the control box. See figures 2 and 3. Contactors are SPST in single phase units and 3PST in three phase units. K1 is energized by the indoor thermostat terminal Y (24V). HP24 units are not equipped with a line voltage to 24V transformer. All 24 VAC controls are powered by the indoor unit. Refer to unit wiring diagram.

2 - Dual Capacitor C12

The compressor and fan in single phase units use permanent split capacitor motors. The capacitor is located inside the unit control box (see figure 2). A single "dual" capacitor (C12) is used for both the fan motor and the compressor (see unit wiring diagram). The fan side and the compressor side of the capacitor have different MFD ratings. See table 1 for dual capacitor ratings.

</tr>
<tr>
<td>HP24-461</td>
</tr>
<tr>
<td>HP24-511/651</td>
</tr>
</tbody>
</table>

3 - Potential Relay K31 (Start)

All single phase units use a potential relay which controls the operation of the starting circuit. The potential relay is located inside the unit control box (see figure 2). The relay is normally closed when contactor K2 is de-energized. When K1 energizes, the compressor immediately begins start-up. K31 remains closed during compressor start-up and start capacitor C7 remains in the circuit. As the compressor gains speed, K31 is energized. When K31 energizes, the contacts open and start capacitor C7 is taken out of the circuit.
4 – Start Capacitor C7
All single phase units use a start capacitor (C7). C7 is
located inside the unit control box (see figure 2). C7 is
wired in parallel with the compressor side of the dual
capacitor. See table 2 for start capacitor ratings.

<table>

</tr>
<tr>
<td>HP24-461/511/651</td>
</tr>
<tr>
<td>HP24-651.2</td>
</tr>
</tbody>
</table>

5 – Timed Off Control A4
A time delay (A4) located in the control box is used on
the HP24-650-2 series. See figures 2 and 3. The time
delay is electrically connected between thermostat
terminal Y and the compressor contactor. After cooling
demand has stopped, A4 begins counting for five
minutes. During the timing period, A4 disables the
compressor contactor. Thermostat demand will have
no effect on the unit. The unit cannot operate. After the
delay, the compressor contactor can be energized.

⚠️ DANGER
Do not attempt to repair this control. Unsafe
operation will result. If the control has failed,
replace the control.

6 – Fan Capacitor C1
The fan in three-phase units uses a single phase
permanent split capacitor motor. A single capacitor C1
is used for the fan motor. C1 is located inside the unit
control box (see figure 3). Table 3 shows the ratings of C1.

<table>

</tr>
<tr>
<td>HP24-463/513/653G</td>
</tr>
<tr>
<td>HP24-513/653J</td>
</tr>
</tbody>
</table>

7 – Transformer T5
Transformer T5 is used on all "J" voltage units. T5 is
used as a step-down transformer for fan B4. T5 is rated at
3.4 VA with a 575 volt primary and a 460 volt secondary.

8 – Defrost Relay K4
The defrost relay controls defrost. The relay is a 3PDT
relay powered 24 VAC from the thermostat. K4 is
enabled during both cooling and heating modes
(except emergency heat). It is only powered when the
defrost control is calling for defrost. When energized,
the reversing valve and indoor auxiliary heat are
energized. Simultaneously, the outdoor fan is de-energized. K4 latches in for the duration of the
defrost period. Refer to unit wiring diagram and
operation sequence in the back of this manual.

9 – Defrost Control CMC1
The CMC1 defrost control (figure 5) is a solid state control
manufactured by Hamilton Standard. The control
provides automatic switching from normal heating
operation to defrost mode and back. The control
provides 14 minute defrost periods at 30, 60 or 90 minute
field changeable intervals. The control monitors
thermostat demand and "holds" the timer in place
between thermostat demand. A set of diagnostic pins are
also provided for troubleshooting the unit.

The control contains a solid state timer which switches
an external defrost relay through 1/4" male spades
mounted on the control's circuit board. When the
defrost thermostat closes (call for defrost), the defrost
timer initiates a 30, 60 or 90 minute (depending on how
the control is preset) timing sequence. If the defrost
thermostat remains closed when the timing sequence
ends, the defrost relay is energized and defrost begins.

---

**SOLID STATE DEFROST CONTROL CMC1**

---

**FIGURE 5**

**Defrost Control Components**

1- **Timing Pins 30, 60, 90**

Each of these pins provides a different timed
interval between defrosts. A jumper connects the
pins to circuit board pin W1. Table 4 shows the
timings of each pin. The defrost interval can be field
changed to 30, 60 or 90 minutes. The defrost period
(14 minutes) cannot be changed. To change the
interval between defrosts, simply remove the
jumper from the pin it is connected to and
reconnect the jumper to one of the other available
pins (see figure 6).

<table>
<thead>
<tr>

</tr>
<tr>
<td>&quot;TST&quot; PINS JUMPER TOGETHER</td>
<td>7 + 0.7 SEC.</td>
</tr>
</tbody>
</table>

---

---
DEFROST CONTROL TIMING CHANGES

WARNING - AVOID CONTACT WITH OTHER CONTROL TERMINALS OR CONTROL COMPONENTS.

WARNING - DO NOT CONNECT TIMING JUMPER TO EITHER “TST” PIN.

TO CHANGE CONTROL TIMINGS:
1- Turn off all power to the unit to avoid circuit board damage.
2- Grasp wire connector firmly with fingers.
3- Gently pull connector from pin.
4- Select new timing pin. DO NOT SELECT A “TST” PIN.
5- Gently push connector onto desired pin (see Table 4 for timings).
6- Turn on power to unit.

FIGURE 6

2- Timing Jumper
The timing jumper is a factory installed jumper on the circuit board used to connect pin W1 to one of the three timing pins. The jumper may be connected to any one of the timing pins but must never be connected to either of the “TST” pins. See Caution below.

CAUTION
Do not connect timing jumper to either “TST” pin. “TST” pins are used only during a test and must not connect with any of the timing pins. Control damage will result.

3- “COM” Terminal
Terminal “COM” provides 24VAC Common.

4- “HLD” Terminal
Terminal “HLD” holds the internal timer in place between thermostat demands and allows the unit to continue timing upon resumption of thermostat demand. Terminal “HLD” is connected directly to thermostat demand.

NOTE – Hold function operates between thermostat demands only when defrost thermostat is closed. This is the only time that the timer is operating.

5- “24V” Terminal
Terminal “24V” receives 24VAC from the control transformer through the defrost thermostat. This terminal powers the control’s internal timer and relays. Terminal “24V” is powered only when there is a call for defrost (defrost thermostat closed). The timer begins timing at 0 only after terminal “24V” receives power.

6- “OUT” Terminal
Terminal “OUT” controls defrost when connected to one side of the defrost relay coil. An internal relay connected to terminal “OUT” closes to allow external defrost relay to energize and initiate defrost. At the end of the defrost period, the internal relay connected to terminal “OUT” opens to de-energize the external defrost relay.

7- “TST” Pins
Each board is equipped with a set of test pins for use in troubleshooting the unit. When jumpered together, these pins reduce the control timing to about 1/256 original time (see Table 4 and figure 7).

IMPORTANT
Control will begin test mode only if normal load is applied to control terminals. Do not attempt to operate or test control out of unit.

DEFROST CONTROL TEST MODE

WARNING - AVOID CONTACT WITH OTHER CONTROL TERMINALS OR CONTROL COMPONENTS.

TO PLACE CONTROL IN TEST MODE:
1- Turn off all power to avoid damaging the circuit board.
2- Make sure all control terminals are connected as shown on unit wiring diagram before attempting to place control in test mode. See NOTE below.
NOTE - Control will not go into test mode when disconnected from unit. Unit load must be applied to control terminals before the control will go into test mode.
3- Connect jumper to “TST” pins as shown.
4- Turn indoor thermostat to heat mode and adjust to highest temperature setting.
5- Turn on power to unit.
6- See Table 4 for control timings in “TST” mode.
7- Be sure to turn off power and remove jumper when test is complete. Turn on power and re-adjust thermostat.

FIGURE 7

A defrost period can last up to 14 minutes and can be terminated two ways. If the defrost thermostat does not open within 14 minutes after defrost begins, the timer will de-energize the defrost relay and the unit will resume normal operation. If the defrost thermostat opens during the 14 minute defrost period, the defrost relay is de-energized and the unit resumes normal operation. Refer to figure 8.

*Shipped with conventional white oil (Sorotex 200LT) or 3GS. 3GS oil may be used if additional oil is required.
**Shipped with 60% Zerol 300—40% Sorotex 200LT. Zerol 300 may be used if additional oil is required.

1 - Rotary Compressor (-141 Units Only)

HP24-141 units utilize a hermetically sealed rotary-type compressor manufactured by Tecumseh Products. It is illustrated in figure 9.

The compressor has four moving parts: a rotor shaft, eccentric, roller and a blade. See figure 10.

The compressor rotor shaft is attached directly to the compressor motor. The rotor shaft is permanently attached to an eccentric. The eccentric is inside the roller and as the eccentric rotates, the roller rotates. The spring loaded blade is in continuous contact with the roller. The contact and a thin layer of oil form a seal separating the suction port from the discharge port at all times.
2 – Accumulator
All HP24-141, 460, 510 and 650 units are equipped with an accumulator that is mounted on the suction line. The accumulator protects the compressor from liquid slugging. Refer to figures 1 and 22.

3 – Reciprocating Compressor (all other units)
All units except the -141 units utilize a conventional reciprocating compressor.

4 – Crankcase Heater
A crankcase heater is used on all HP24–211 through HP24–650 models. The well-mounted insertion-type heater is self-regulating. See table 6 for crankcase heater specifications. Crankcase heater is optional on -141 units.

<table>

</tr>
</tbody>
</table>

5 – Compressor Cover (Figure 12)
A compressor cover constructed of vinyl-faced fiberglass is used on all HP24–261 through -650 units. The cover provides an acoustic barrier. The cover slides over the compressor and is held secure with velcro straps. Slits are provided for installation around the discharge and suction lines.

C – Outdoor Fan Motor
All units use single-phase PSC fan motors which require a run capacitor. The table on page 1 of this manual shows the specifications of outdoor fans used in HP24s. In all units, the outdoor fan is controlled by the compressor contactor and defrost relay.

Two different mounting arrangements are used (fan up and fan motor up) see figures 13 and 14.

Access to the outdoor fan motor on all units is gained by removing the six screws securing the fan guard. See figures 13 and 14. The outdoor fan motor is attached to the fan guard on "motor up" units and is removed with the fan guard. See figure 13.
D – Reversing Valve L1 and Solenoid

A refrigerant reversing valve with electromechanical solenoid is used to reverse refrigerant flow during unit operation. The reversing valve requires no maintenance. It is not rebuildable. If the reversing valve has failed, it must be replaced. If replacement is necessary, access the reversing valve by removing the control box. HP24-460 through -650 series units have a filler panel that can also be removed for reversing valve access. Refer to figure 15.

III – REFRIGERANT SYSTEM

Refer to figures 16, 17 and 18 for refrigerant flow in the heating and cooling modes. The reversing valve is energized during cooling demand and during defrost.
A - Service Valves

The liquid line and vapor line service valves and gauge ports are accessible from outside of the unit. Full service liquid and vapor line valves are used. See figures 19 and 20. The service ports are used for leak testing, evacuating, charging and checking charge.

1 - Liquid Line Service Valve

A full-service liquid line valve made by one of several manufacturers may be used. All liquid line service valves function the same way, differences are in construction. Valves manufactured by Parker are forged assemblies. Valves manufactured by Primore are brazed together. Valves are not rebuildable. If a valve has failed it must be replaced. The liquid line service valve is illustrated in figure 19. The valve is equipped with a service port. There is no schrader valve installed in the liquid line service port. A service port cap is supplied to seal off the port. The liquid line service valve is a front and back seating valve. When the valve is backseated the service port is not pressurized. The service port cap can be removed and gauge connections can be made.

⚠️ CAUTION

The service port cap is used to seal the liquid line service valve. Access to service port requires backseating the service valve to isolate the service port from the system. Failure to do so will cause refrigerant leakage.
To Access Service Port:
1. Remove the stem cap. Use a service wrench (part #18P66, 54B64 or 12P95) to make sure the service valve is backseated.
2. Remove service port cap and connect high pressure gauge to service port.
3. Using service wrench, open valve stem (one turn clockwise) from backseated position.

4. When finished using port, backseat stem with service wrench. Tighten firmly.
5. Replace service port and stem cap. Tighten finger tight, then tighten an additional 1/6 turn.

To Close Off Service Port:
1. Using service wrench, backseat valve.
   a. Turn stem counterclockwise.
   b. Tighten firmly.

To Open Liquid Line Service Valve:
1. Remove the stem cap with an adjustable wrench.
2. Using service wrench, backseat valve.
   a. Turn stem counterclockwise until backseated.
   b. Tighten firmly.
3. Replace stem cap, finger tighten then tighten an additional 1/6 turn.

To Close Liquid Line Service Valve:
1. Remove the stem cap with an adjustable wrench.
2. Turn the stem in clockwise with a service wrench to front seat the valve. Tighten firmly.
3. Replace stem cap, finger tighten then tighten an additional 1/6 turn.

2 - Vapor Line Service Valve

**WARNING**
Do not attempt to backseat this valve. Attempts to backseat this valve will cause snap ring to explode from valve body under pressure of refrigerant. Personal injury and unit damage will result.

A full service non-backseating vapor line service valve is used on all HP24 series units. Different manufacturers of valves may be used. All vapor line service valves function the same way, differences are in construction. Valves manufactured by Parker are forged assemblies. Valves manufactured by Primore are brazed together. Valves are not rebuildable. If a valve has failed it must be replaced. The vapor line service valve is illustrated in figure 20.

The valve is equipped with a service port. A schrader valve is factory installed. A service port cap is supplied to protect the schrader valve from contamination and assure a leak free seal.

To Access Schrader Port:
1. Remove service port cap with an adjustable wrench.
2. Connect gauge to the service port.
3. When testing is completed, replace service port cap. Tighten finger tight, then tighten an additional 1/6 turn.
To Open Vapor Line Service Valve:
1 – Remove stem cap with an adjustable wrench.
2 – Using service wrench and 5/16" hex head extension (part #49A71) back the stem out counterclockwise until the valve stem just touches the retaining ring.
3 – Replace stem cap tighten firmly. Tighten finger tight, then tighten an additional 1/6 turn.

To Close Vapor Line Service Valve:
1 – Remove stem cap with an adjustable wrench.
2 – Using service wrench and 5/16" hex head extension (part #49A71) turn stem in clockwise to seat the valve. Tighten firmly.
3 – Replace stem cap. Tighten finger tight, then tighten an additional 1/6 turn.

B – Plumbing
See figures 21 and 22 for unit refrigerant components. Field refrigerant piping consists of liquid and vapor lines from the outdoor unit (sweat connections). Use Lennox L10 series line sets as shown in table 7 or field fabricated refrigerant lines.

IV – CHARGING

Units manufactured before September 1, 1992 have a sufficient charge for a 25ft. line set. Units manufactured after September 1, 1992 have sufficient charge for a 20ft. line set. Refer to unit nameplate for factory supplied charge.

Unit charge is based on a matching indoor coil and outdoor coil with a 20 or 25 foot (6096 or 7620 mm) line set depending on date of manufacture. For varying lengths of line set, refer to table 8.

*If line set is greater than 20 ft. (610mm) or 25 ft. (762mm) depending on date of unit manufacture add this amount. If line set is less than 20 ft. (610mm) or 25 ft. (762mm) depending on date of unit manufacture subtract this amount.
A - Pumping Down System

**CAUTION**

Deep vacuum operation (operating compressor below 0 psig) can cause internal fusite arcing resulting in a damaged or failed compressor. This type of damage will result in denial of warranty claim.

1. Attach gauge manifold.
2. Front seat (close) liquid line valve.
3. Start outdoor unit in cooling mode.
4. Monitor suction gauge. Stop unit when 0 psig is reached.
5. Front seat (close) suction line valve.
B – Evacuating the System
1– Attach gauge manifold. Connect vacuum pump (with vacuum gauge) to center port of gauge manifold. With both manifold service valves open, start pump and evacuate indoor coil and refrigerant lines.

IMPORTANT
A temperature vacuum gauge, mercury vacuum (U-tube), or thermocouple gauge should be used. The usual Bourdon tube gauges are not accurate enough in the vacuum range.

IMPORTANT
The compressor should never be used to evacuate a refrigeration or air conditioning system.

2– Evacuate the system to 29 inches (737mm) vacuum. During the early stages of evacuation, it is desirable to stop the vacuum pump at least once to determine if there is a rapid loss of vacuum. A rapid loss of vacuum would indicate a leak in the system and a repeat of the leak testing section would be necessary.

3– After evacuating system to 29 inches (737mm), close gauge manifold valves to center port, stop vacuum pump and disconnect from gauge manifold. Attach an upright nitrogen drum to center port of gauge manifold and open drum valve slightly to purge line at manifold. Break vacuum in system with nitrogen pressure by opening manifold high pressure valve. Close manifold high pressure valve to center port.

4– Close nitrogen drum valve and disconnect from gauge manifold center port. Release nitrogen pressure from system.

5– Connect vacuum pump to gauge manifold center port. Evacuate system through manifold service valves until vacuum in system does not rise above 29.7 inches (754mm) mercury (5mm absolute pressure) within a 20–minute period after stopping vacuum pump.

6– After evacuation is complete, close manifold center port, and connect refrigerant drum. Pressurize system slightly with refrigerant to break vacuum.

C – Leak Testing (To Be Done Only After Pump Down)
1– Attach gauge manifold and connect a drum of dry nitrogen to center port of gauge manifold.

2– Open high pressure valve on gauge manifold and pressurize line set/indoor coil to 150 psig (1034 kPa).

3– Check lines and connections for leaks.
4– Release nitrogen pressure from the system, correct any leaks and recheck.

CAUTION
When using dry nitrogen, a pressure reducing regulator must be used to prevent excessive pressure in gauge manifold, connecting hoses, and within the system. Regulator setting must not exceed 150 psig (1034 kpa). Failure to use a regulator can cause equipment failure resulting in injury.

NOTE: If electronic leak detector is used, add a trace of refrigerant to the nitrogen for detection by the leak detector.

D – Charging
Charging must be done in the cooling mode. If system is completely void of refrigerant, the recommended and most accurate method of charging is to weigh the refrigerant into the unit according to the total amount shown on the unit nameplate and in table 9. Separate discharge and vapor line service ports are provided outside the unit for connection of gauge manifold during charging procedure as well as a suction line service port.

*Charges in ft lb are for units manufactured after September 1, 1992.

If weighing facilities are not available or if unit is just low on charge, the following procedure applies. RFC and TXV systems use different charging methods.

1 – Expansion Valve Systems
The following procedures are intended as a general guide for use with expansion valve systems only. For best results, indoor temperature should be between 70 °F and 80 °F. If outdoor temperature is 60 °F (16 °C) or above the approach method of charging is used. If outdoor temperature is less than 60 °F (16 °C) the subcooling method of charging is used. Slight variations in charging temperature and pressure should be expected. Large variations may indicate a need for further servicing.
**IMPORTANT**

The following procedures require accurate readings of ambient (outdoor) temperature, liquid temperature and liquid pressure for proper charging. Use a thermometer with accuracy of ±2°F and a pressure gauge with accuracy of ±5 PSIG.

**APPROACH METHOD (TXV SYSTEMS)**
*(Ambient Temperature of 60°F [16°C] or Above)*

1. Connect gauge manifold. Connect an upright R-22 drum to center port of gauge manifold.
2. Record outdoor air (ambient) temperature.
3. Operate indoor and outdoor units in cooling mode. Allow outdoor unit to run until system pressures stabilize.
4. Make sure thermometer well is filled with mineral oil before checking liquid line temperature.
5. Place thermometer in well and read liquid line temperature. Liquid line temperature should be a few degrees warmer than the outdoor air temperature. Table 10 shows how many degrees warmer the liquid line temperature should be.

Add refrigerant to make the liquid line temperature cooler.

Recover refrigerant to make the liquid line temperature warmer.

**FIGURE 23**

1. Connect gauge manifold. Connect an upright R-22 drum to center port of gauge manifold.
2. Operate indoor and outdoor units in cooling mode. Allow outdoor unit to run until system pressures stabilize.
3. Make sure thermometer well is filled with mineral oil before checking liquid line temperature.
4. Read liquid line pressure and convert to condensing temperature using temperature/pressure conversion chart.

Condensing temperature (read from gauges) should be a few degrees warmer than the liquid line temperature.

5. Place thermometer in well and read liquid line temperature. Table 11 shows how much warmer the condensing temperature should be. Add refrigerant to make the liquid line temperature cooler.

Recover refrigerant to make the liquid line temperature warmer.

</tbody>
</table>

6. When unit is properly charged liquid line pressures should approximate those given in Table 12.

**SUBCOOLING METHOD (TXV SYSTEMS)**
*(Ambient Temperature Below 60°F [16°C] )*

**NOTE:** It may be necessary to restrict air flow in order to reach liquid pressures in the 200-250 psig range which are required for checking charge. Block equal sections of air intake panels as shown in figure 23, moving obstructions sideways until liquid pressures in the 200-250 psig range are reached.

**IMPORTANT**

Use Table 12 as a general guide for performing maintenance checks. Table 12 is not a procedure for charging the system. Minor variations in pressures may be expected due to differences in installations. Significant deviations may mean the system is not properly charged or that a problem exists with some component in the system. Used prudently, Table 12 could serve as a useful service guide.
2 – RFCII Systems

The system should not be charged at ambient below 60 °F (15 °C). If charging below 60 °F (15 °C) is required, the recommended method of charging is to weigh the refrigerant into the unit according to the total amount shown on the unit nameplate and in table 9. For line sets varying from 20 or 25 feet (depending on date of manufacture), refer to table 8 for refrigerant charge adjustment. If ambient temperature is above 60 °F (15 °C) use the subcooling method outlined below.

**SUBCOOLING METHOD (RFCII SYSTEMS)**
(Ambient Temperature Above 60 °F [16 °C])

1. Connect gauge manifold. Connect an upright R-22 drum to center port of gauge manifold.

2. Operate indoor and outdoor units in cooling mode. Allow outdoor unit to run until system pressures stabilize.

3. Make sure thermometer well is filled with mineral oil before checking liquid line temperature.

4. Read liquid line pressure and convert to condensing temperature using temperature/pressure conversion chart.

Condensing temperature (read from gauges) should be a few degrees warmer than the liquid line temperature.

*Approved match-ups only

5. Place thermometer in well and read liquid line temperature. Table 13 shows how much warmer the condensing temperature should be.

Add refrigerant to make the liquid line temperature cooler.

Recover refrigerant to make the liquid line temperature warmer.

6. When unit is properly charged liquid line pressures should approximate table 12.

E – Oil Charge

Refer to table 5 on page 6 for factory oil charge.

V – Maintenance

At the beginning of each heating or cooling season, the system should be cleaned as follows:

A – Outdoor Unit

1. Clean and inspect outdoor coil. (Coil may be flushed with a water hose).

2. Outdoor fan motor is prelubricated and sealed. Relubricate motor according to instructions on the motor manufacturer's nameplate.

3. Visually inspect all connecting lines, joints and coils for evidence of oil leaks.

**NOTE:** If insufficient heating or cooling occurs, unit should be gauged and refrigerant charge checked.

B – Indoor Coil

1. Clean coil if necessary.

2. Check connecting lines, joints and coil for evidence of oil leaks.

3. Check condensate line and clean if necessary.

C – Indoor Unit

1. Clean or change filters.

2. Check blower motor for debris. Blower motors are prelubricated and sealed. No further lubrication required.

3. Adjust blower speed for cooling. The static pressure drop over the coil should be checked to determine the correct blower CFM. Refer to Lennox Engineering Handbook for Static Pressure and CFM tables.

4. Check all wiring for loose connections.

5. Check for correct voltage at unit.

6. Check amp-draw on blower motor.

Unit nameplate_______Actual______
HP24 SINGLE PHASE OPERATING SEQUENCE

A-HP24 P Voltage Operation Sequence

This is the sequence of operation for HP24 "P" voltage units. The sequence is outlined by numbered steps which correspond to circled numbers on the adjacent diagram.

NOTE – The thermostat used may be electromechanical or electronic.
NOTE – Transformer in indoor unit supplies power (24 VAC) to the thermostat and outdoor unit controls.

COOLING:

1 – Cooling demand initiates at Y1 in the thermostat. Internal thermostat wiring energizes terminal Q energizing the reversing valve L1.
2 – Compressor contactor K1 is energized.
3 – K1-1 N.O. closes energizing compressor (B1) and outdoor fan motor (B2). Compressor (B1) and outdoor fan motor (B4) begin immediate operation.

END OF COOLING DEMAND:

4 – Cooling demand is satisfied. Terminal Y1 is de-energized.
5 – Terminal Q and reversing valve L1 are de-energized.
6 – Compressor contactor K1 de-energized.
7 – K1-1 N.O. closes de-energizing compressor and outdoor fan motor. Compressor (B1) and outdoor fan motor (B4) begin immediate operation.

FIRST STAGE HEAT:

8 – Heating demand initiates at W1 in the thermostat. Compressor contactor K1 is energized.
9 – K1-1 N.O. closes energizing compressor and outdoor fan motor. Compressor (B1) and outdoor fan motor (B4) begin immediate operation.

END OF FIRST STAGE HEAT:

10 – Heating demand is satisfied. Terminal W1 is de-energized.
11 – Compressor contactor K1 de-energized.
12 – K1-1 opens and compressor (B1) and outdoor fan motor (B4) are de-energized and stop immediately.

AUXILIARY HEAT (SECOND STAGE):

13 – Additional heating demand initiates at W3 in the thermostat. Outdoor unit remains running. W1 of indoor unit terminal strip TB1 is energized initiating first stage heat from indoor unit.
14 – If outdoor temperature is below the balance point, N.O. low ambient cut in thermostat S23 will close.
15 – When S23 is closed, W2 of indoor unit terminal strip TB1 is energized initiating second stage heat from indoor unit.

END OF AUXILIARY HEAT (SECOND STAGE):

16 – Heating demand is satisfied. Terminal W3 is de-energized. Indoor unit heating operation stops and outdoor unit continues operation.

EMERGENCY HEAT:

17 – Emergency heat mode is set at the thermostat. Outdoor unit will not be operational in this mode. Terminal E2 is energized in the thermostat. Emergency heat relay K26 is energized.
18 – N.O. K26-1 closes energizing W1 and W2 on terminal strip TB1 of indoor unit. Indoor unit operates in second stage heat mode.

DEFROST MODE:

19 – During heating operation when outdoor coil temperature drops below 35° ± 4° F Defrost Switch (thermostat) S6 closes.
20 – Defrost control CMC1 begins timing. If defrost thermostat (S6) remains closed at the end of the 30, 60 or 90 minute period, defrost relay K4 energizes and defrost begins.
21 – N.O. K4-3 closes energizing the reversing valve.
22 – N.O. K4-1 closes energizing W1 on TB1 terminal strip of indoor unit. Indoor unit operates in the first stage heat mode.
23 – N.C. K4-2 opens and outdoor fan motor B4 stops.
24 – Defrost continues 14 ± 1 minutes or until thermostat switch (S6) opens. When defrost thermostat opens defrost control CMC1 loses power and resets.
25 – Defrost relay K4 is de-energized.
26 – K4-1 opens and W1 on terminal strip TB1 of indoor unit is de-energized.
27 – K4-2 closes and the outdoor fan begins operation.
28 – K4-3 opens de-energizing the reversing valve.
HP24 THREE PHASE OPERATING SEQUENCE

A-HP24 (Y, G and J Voltage) Operation Sequence

This is the sequence of operation for HP24 "Y", "G" and "J" voltage units. The sequence is outlined by numbered steps which correspond to circled numbers on the adjacent diagram.

NOTE--The thermostat used may be electromechanical or electronic.
NOTE--Transformer in indoor unit supplies power (24 VAC) to the thermostat and outdoor unit controls.

COOLING:
1 - Cooling demand initiates at Y1 in the thermostat. Internal thermostat wiring energizes terminal O energizing the reversing valve L1.
2 - Compressor contactor K1 is energized.
3 - K1-1 N.O. closes energizing compressor (B1) and outdoor fan motor (B1). Compressor (B1) and outdoor fan motor (B4) begin immediate operation.

END OF COOLING DEMAND:
4 - Cooling demand is satisfied. Terminal Y1 is de-energized.
5 - Terminal O and reversing valve L1 are de-energized
6 - Compressor contactor K1 is de-energized.
7 - K1-1 opens and compressor (B1) and outdoor fan motor (B4) are de-energized and stop immediately.

FIRST STAGE HEAT:
8 - Heating demand initiates at W1 in the thermostat. Compressor contactor K1 is energized.
9 - K1-1 N.O. closes energizing compressor and outdoor fan motor.
10 - Compressor (B1) and outdoor fan motor (B4) begin immediate operation.

END OF FIRST STAGE HEAT:
11 - Heating demand is satisfied. Terminal W1 is de-energized. Compressor contactor K1 is de-energized.
12 - K1-1 opens and compressor (B1) and outdoor fan motor (B4) are de-energized and stop immediately.

AUXILIARY HEAT (SECOND STAGE):
13 - Additional heating demand initiates at W3 in the thermostat. Outdoor unit remains running.
14 - W1 of indoor unit terminal strip TB1 is energized initiating first stage heat from indoor unit.
15 - If outdoor temperature is below the balance point, N.O. low ambient cut in thermostat S23 will close.
16 - When S23 is closed, W2 of indoor unit terminal strip TB1 is energized initiating second stage heat from indoor unit.

END OF AUXILIARY HEAT (SECOND STAGE):
17 - Heating demand is satisfied. Terminal W3 is de-energized.
18 - Indoor unit heating operation stops and outdoor unit continues operation.

EMERGENCY HEAT:
19 - Emergency heat mode is set at the thermostat. Outdoor unit will not be operational in this mode. Terminal E2 is energized in the thermostat.
20 - Emergency heat relay K26 is energized.
21 - N.O. K26-1 closes energizing W1 and W2 on terminal strip TB1 of indoor unit. Indoor unit operates in second stage heat mode.

DEFROST MODE:
22 - During heating operation when outdoor coil temperature drops below 35°F, defrost control CMC1 begins timing. If defrost thermostat (S6) remains closed at the end of the 30, 60 or 90 minute period, defrost relay K4 energizes and defrost begins.
23 - N.O. K4-3 closes energizing the reversing valve.
24 - N.O. K4-1 closes energizing W1 on terminal strip of indoor unit. Indoor unit operates in the first stage heat mode.
25 - N.C. K4-2 opens and outdoor fan motor B4 stops.
26 - Defrost continues 14 ± 1 minutes or until thermostat switch (S6) opens. When defrost thermostat opens defrost control CMC1 loses power and resets.
27 - Defrost relay K4 is de-energized.
28 - K4-1 opens and W1 on terminal strip TB1 of indoor unit is de-energized.
30 - K4-2 closes and the outdoor fan begins operation.
31 - K4-3 opens de-energizing the reversing valve.
